This Talk

Work done jointly with:

- *Razieh Behjati (PhD)*
- *Dr. Lionel Briand*
- *Dr. Tao Yue*

About the Project (Part 1)

The Domain: Subsea Production Systems

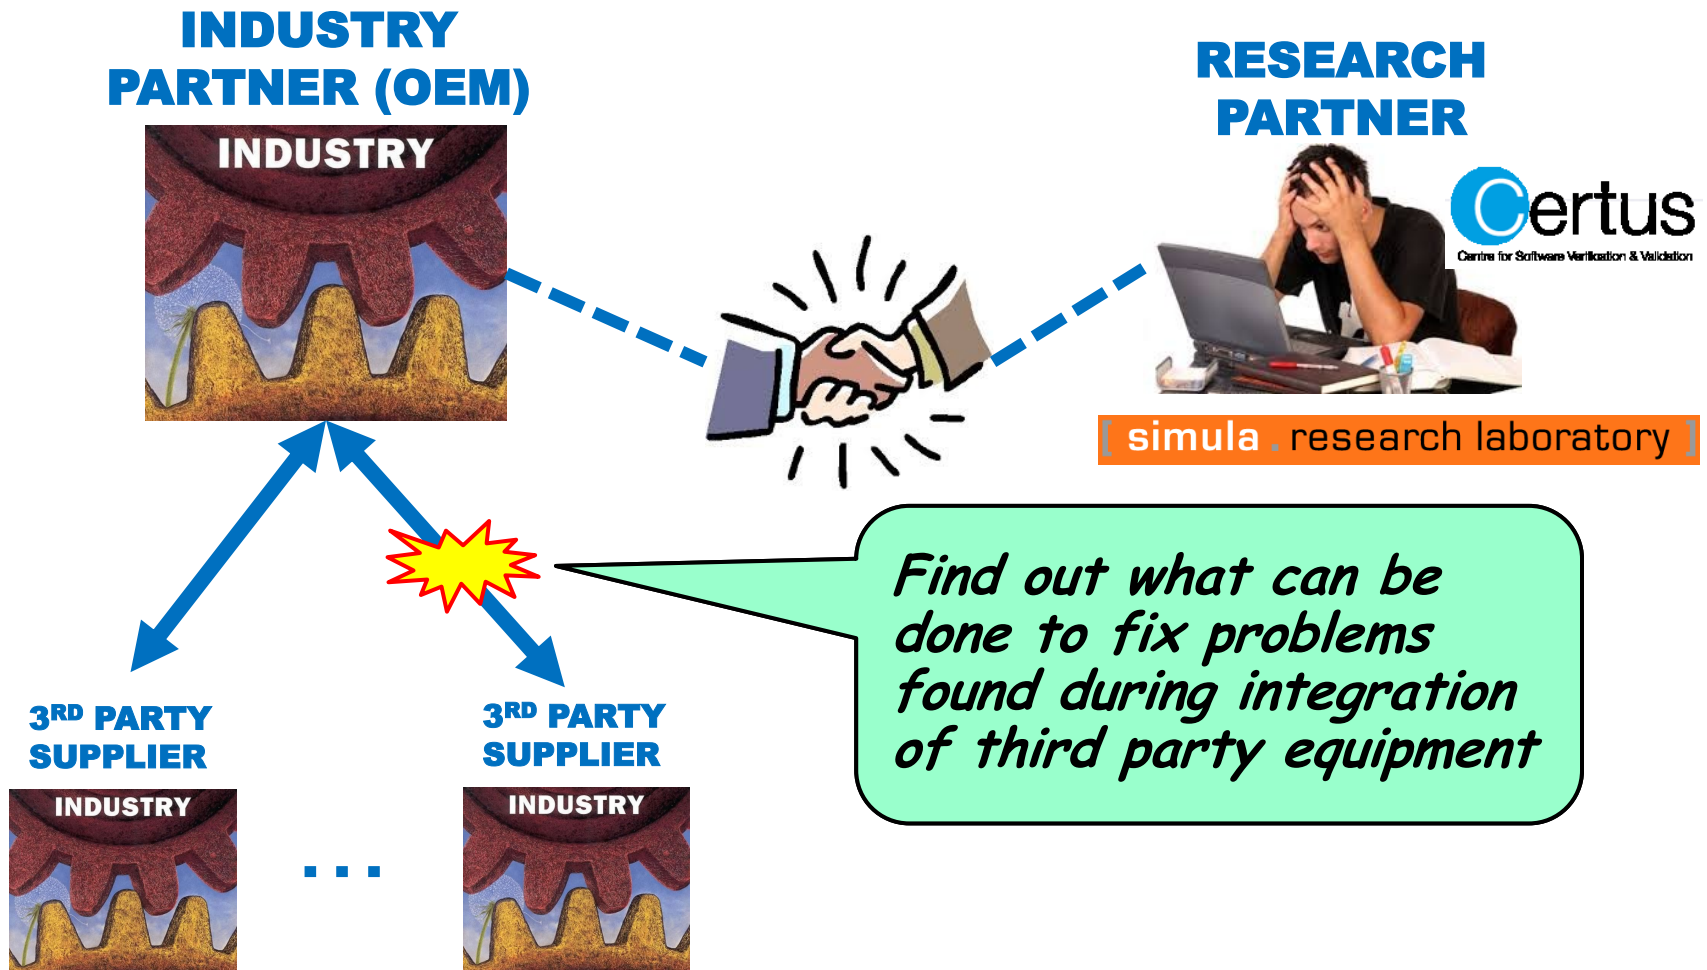

- ◆ Complex technologically heterogeneous systems:

Complex Heterogeneous Systems

- ♦ Aerospace, automotive, manufacturing, medical equipment, nautical systems, office equipment, telecommunications, etc.
 - Mature disciplines based on traditional engineering technologies and knowledge and mostly tangible artifacts
- ♦ Software is generally a late-comer to this world
 - Evolved from simple relay-logic replacements to fully-fledged integrated control systems (e.g., ~100MLoC)
 - A key source of value add and market differentiation
- ♦ Unfortunately, it is still not fully understood in enterprises dominated by more traditional skills
- ♦ Cyber-physical systems: an approach advocating designing systems as a whole

The Project

A typical industry-research collaboration project

Industry Partner

- ◆ Market leader in subsea oil & gas extraction systems

- OEM (system integrator) role
- Major development team in Norway

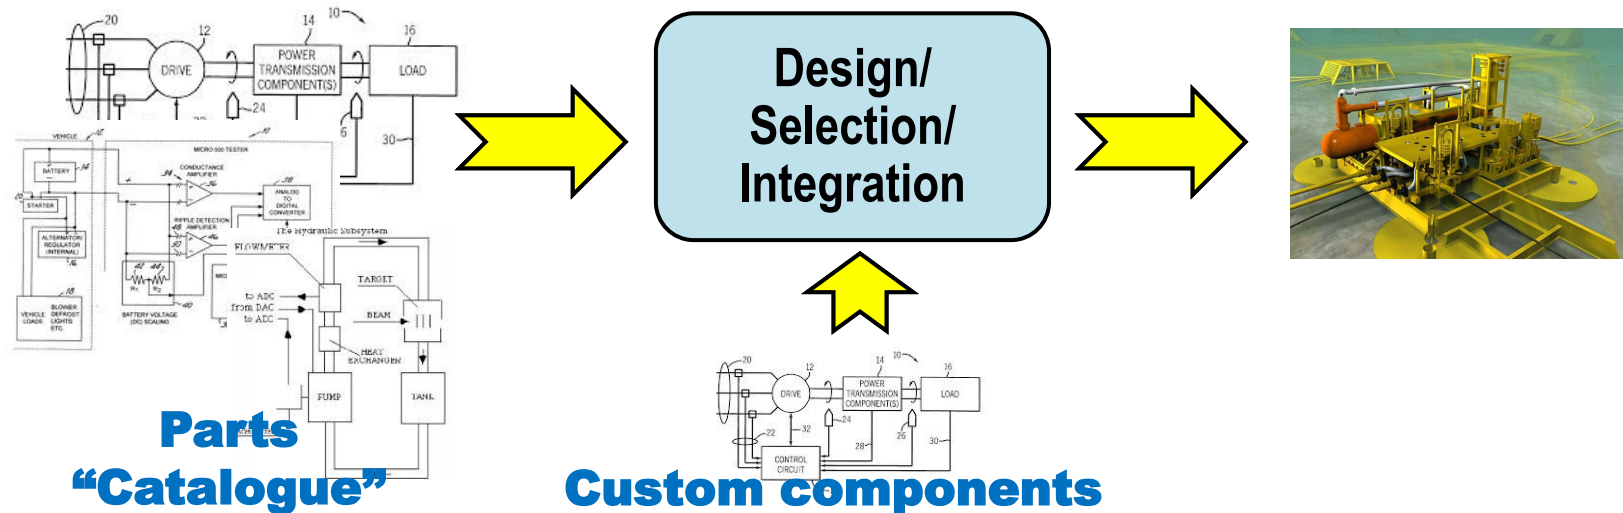

- ◆ Characteristics:

- Dominated by traditional engineering culture
- The role and significance of software in products growing rapidly
- But, still perceived as a *follow-on component* component

The Product Line and Products

- ♦ Structured “catalogue” of mechanical, hydraulic, electronic, communications, and computing components

- ♦ A particular system (product) is constructed by a customer-specific configuration of standard and custom components produced by the OEM and subcontractors

[simula . research laboratory]

- ♦ A specialized research institute owned and funded by the government of Norway
 - Focus on software and communications technologies
 - Established in 2001 and conceived as an unfettered institution for researchers
 - No teaching duties, no funding proposals, minimal admin overhead
 - ~35 research staff
- ♦ Several research departments
 - Includes the Certus Centre within the Software Engineering department

The Certus Centre (1)

- ♦ An 8-year project funded by the Research Council of Norway
 - ~16 people (primarily senior researchers and PhD candidates)
 - ~75M NOK (~\$13M or \$2.6M/yr)
 - Head: Dr. Arnaud Gotlieb (previously: Dr. L. Briand)
- ♦ One of 16 Norwegian Centres for Research-Based Innovation (SFI)
 - Created to “encourage enterprises to innovate through collaboration with advanced research groups”
 - *i.e., industrially-relevant research*

The Certus Centre (2)

- ♦ Focus on verification and validation of software
- ♦ 4 main projects (involving user partners)
 - *Model-based engineering of highly configurable systems*
 - Safety analysis and certification of embedded systems
 - Testing of data-intensive systems
 - Testing of real-time embedded systems
- ♦ Characteristics:
 - 5 user partners (1 government, 3 industry, 1 tool vendor)
 - Partners only need to provide in-kind contributions ⇒ practically free *government-funded research*

Detour (1): On Industry-Research Collaborations in Software Engineering Research

Who Am I to Talk About Research?

- ♦ Most of my career (40+ years in software engineering) has been in industry
 - Some academic experience (teaching, adjunct)
- ♦ I have been and am currently involved in industry-research collaboration projects and know from experience that they can be highly successful:
 - Worked in and with a number of research institutes
 - Directly involved as an industry participant in numerous industry-research collaboration projects
 - Acted as expert referee/reviewer of many research proposals and evaluations in Europe and North America
 - Previously: on Board of Directors of three research funding bodies

Key Question

RESEARCH

What makes an industry-research collaboration projects successful?

Industry-Research Collaboration Projects

Technical projects in which:

- (a) one or more industry partners define the problem and provide domain expertise and*
- (b) an institution specializing in research seeks to provide a solution*

- ♦ Rationale: Industry might be lacking
 - Resources (time, budget) needed to conduct research
 - Technical expertise:
 - Not a question of ability, but of a systematic and comprehensive understanding of the state of the art

Objectives: Industry Partner

- ♦ Fixing specific point problems not satisfactorily solvable by current practices or technologies
- ♦ Improving productivity and/or product quality (i.e., doing things better)
- ♦ Demonstrating technical leadership: public relations (PR) benefit
- ♦ Identifying new technical/product opportunities
- ♦ Gaining a systematic and comprehensive understanding of the problem and solution spaces
- ♦ Access to potential highly-qualified hires

Objectives: Research Partner

- ♦ Increasing likelihood of future funding
- ♦ Working on technical challenges that may advance the state of the art
- ♦ Enhancing own scientific reputation
 - generally supplements the first two items
- ♦ Training of highly-qualified personnel
 - PhD, MSc, postdoc
- ♦ Solving industry partner problems

Types of (Software) Research Institutions

- ♦ **Corporate (in house) research groups**
 - Large enterprises: IBM Research, Bell Labs, Google, Microsoft Research, Tata Consultancy Services, etc.
 - SME advanced technology departments
- ♦ **Independent research groups**
 - Academic (university) research teams
 - Government-supported specialized research institutes

Corporate Research Groups: Analysis

- ♦ (Pro) Intellectual property protected
- ♦ (Pro) Tighter interworking with industry partner
- ♦ (Con) Expensive
- ♦ (Con) Often disconnected from corporate mainstream
 - In some cases, exist primarily for corporate PR value (little interest in research results)
 - Not seen by production teams as a primary source of advanced solutions ⇒ self-fulfilling prophecy
- ♦ Strong corporate pressure to be “relevant”
 - Frequently turn into specialized product development shop
 - But, typically *more expensive than development*

Independent Research Groups: Analysis

- ♦ (Pro) Cheaper and more easily directed than corporate (for industry partners)
 - ♦ (Con) IP concerns
 - ♦ Industry-relevant research is often deemed “second rate” by academics
 - “Insufficiently “scientific”, “tainted by commercialism”
 - E.g., separate proceedings for “industrial tracks”
 - Concern that pragmatic concerns will obscure the essence
- ⇒ Many academics avoid this type of research (pro/con?)
- ♦ Conversely, research institutes often favour this type of research
 - Typically part of their mandate

Challenge: Engaging Suitable Industry Partners

- ♦ Despite all their advantages, independent research institution usually have difficulties to:
 - Find partners willing to commit resources to research
 - Especially if a cash contribution is required
 - Get access to industry experts at required levels
 - Transfer research results to industry partners
- ♦ Why?

Hurdles

- ♦ Need to find strong insider advocates who:
 - Understand the need for research
 - Have necessary corporate leverage to commit
 - Are persistent
- ♦ The significance of software is still not sufficiently understood by many corporate decision makers
 - Traditional engineering culture with minimal software training
 - Value proposition not sufficiently understood
- ♦ IP leakage and ownership concerns
- ♦ Short-term corporate mindset/culture...

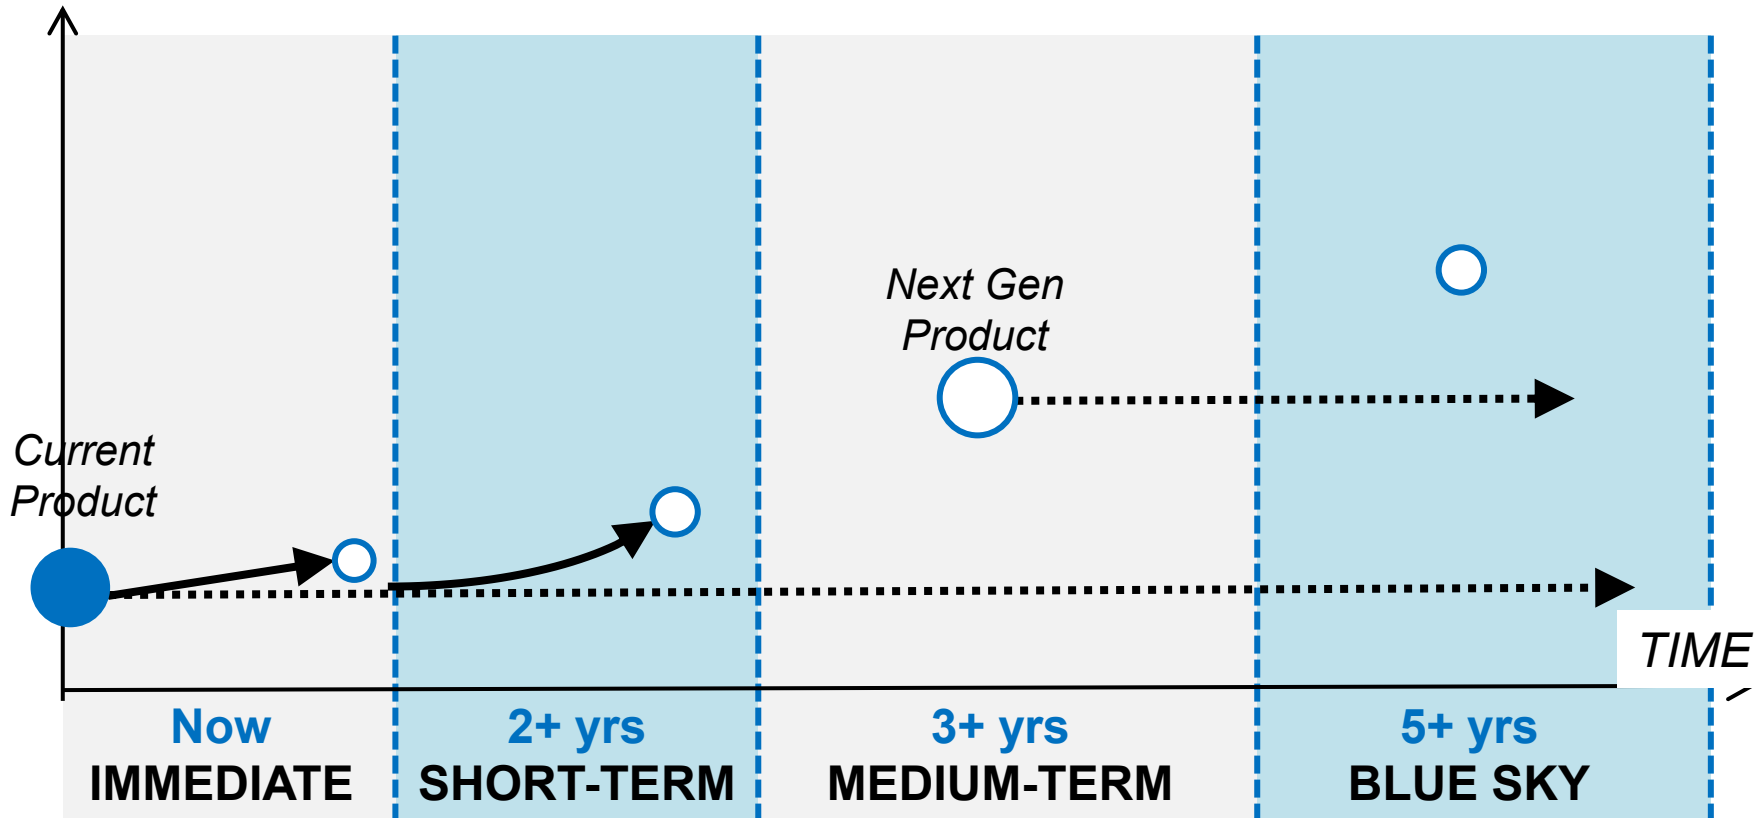

The Research vs Short-Term Profit Conundrum

- ♦ Corporations, particularly publically-traded ones, face strong market pressures to meet quarterly profit projections
 - Focus is on short-term results
 - Research value is hard to prove
("Making predictions is hard, especially about the future" -- Y. Berra)
 - Draws resources away from research
 - *"Do I sacrifice my project (and my bonus) or the corporate future?"*

Categories of Industrial Research

DEGREE OF
INNOVATION

NB: Provisional informal categorization

Immediate Type Research

- ◆ **Scope: within 1-2 years**
- ◆ **Address current problems in existing products**
- ◆ **Practitioners often lack requisite overview of the problem space and/or available solutions**
 - Point (vs. “systematic”) solutions to problems
 - Researchers can provide a systematic and comprehensive view
- ◆ **Possibly the “sweet spot” for industry-research collaboration (for both parties)**
 - Greatest likelihood of results being adopted in practice
 - But, is it “research”?
 - Tends to be respected less in academia

Short-Term Research

- ◆ Scope: 2-4 years
- ◆ Address near-term anticipated problems and developments related to existing products
 - e.g., possible new features, scalability/performance problems, introduction of new technologies, new methods and tools
- ◆ Typically lower corporate commitment to adoption than short-term research
 - Issues less pressing
- ◆ Better suited to academic research groups

Next-Gen Product (Medium-Term) Research

- ◆ Invariably undertaken by corporate research groups (due to IP concerns)
- ◆ Usually work on a 3+ year horizon
 - Proof-of-concept technological prototypes
 - New product architecture
- ◆ **[Experience]** Most next-gen projects are abandoned!
- ◆ In practice, most next-gen products are conceived and realized by development groups (vs. research groups)
 - Greater corporate leverage (and experience)
 - Seen as a lower risk option by decision makers
 - But, proposed technological advancement often either
 - [1] undershoots (“same old”) or
 - [2] overshoots (“the second system syndrome”)

Blue Sky (Long-Term) Research

- ♦ Scope: 5-10 years and beyond
- ♦ Deals with topics that are not necessarily directly related to current products
 - Usually by corporate research groups (e.g., Bell Labs, IBM Research, Google)
- ♦ [Opinion] Corporate PR value is often primary motivation (particularly for large enterprises)
- ♦ Good opportunity for academic researchers
- ♦ But, funding for such projects is difficult to secure

What About Research Consortia?

- ♦ Groupings of research institutions and industry partners working on a common project
 - E.g., EC funded research projects
 - Creates critical mass that impresses funding agencies
- ♦ [Opinion] Weak synergy
 - Once the funding is secured, very little technical collaboration
 - The “bank robbery syndrome”
 - Research groups enter with their established specialties and biases \Rightarrow impedes effective synergy
- ♦ [Opinion] *industry partners typically get very little value-add out of consortia-type research projects*

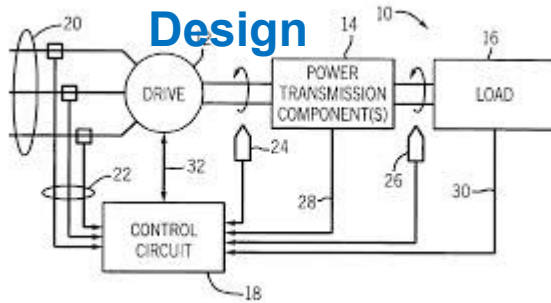

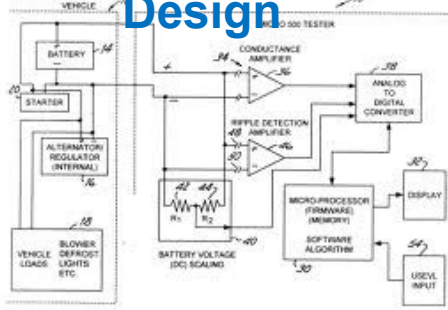

Project Approach and Results (Part 2)

Development Artifacts

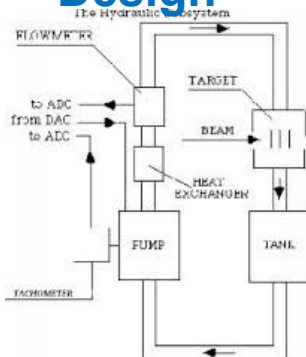

Mechanical Design

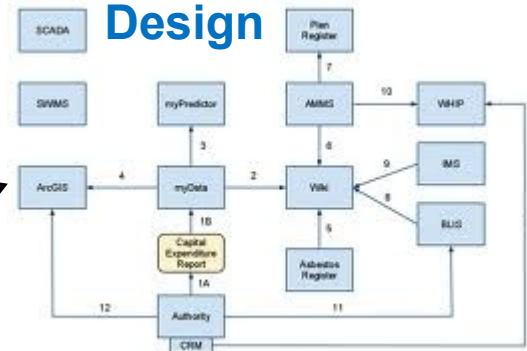

Electrical Design

Hydraulic Design

Software Design

Configuration System Design

Emerges from collected input data

Root Cause Analysis

- ♦ “Integration problems”
 - ♦ Analysis methods:
 - Intensive study of system design documents, requirements documents, error reports, test results
 - Numerous meetings and interviews with domain experts
 - Polls/questionnaires
 - ♦ Conclusions:
 - The vast majority (~50%) of “integration” problems turned out to be errors in configuration*
 - e.g., wrong software driver configured for hardware device
 - Not directly perceived as such by industry partner
- ⇒ *A systematic approach to configuration needed*

Main Sources of Configuration Errors

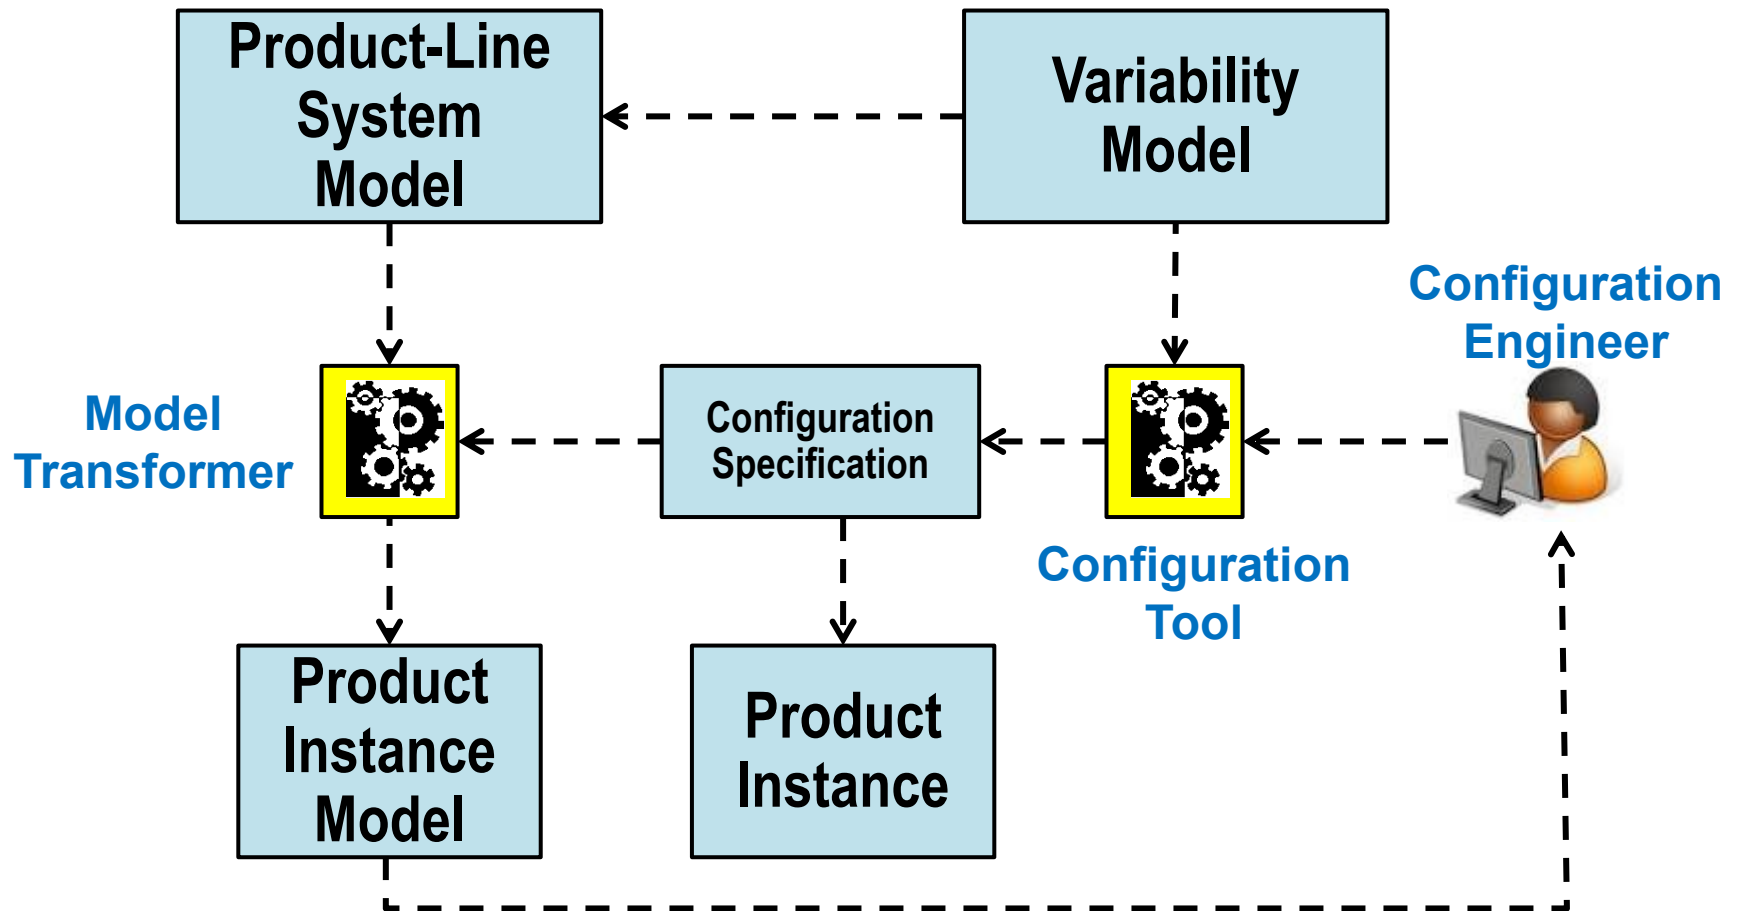

- ◆ Configuration engineers need to have an in-depth understanding of both hardware components and software
 - Difficult to extract from documentation and designers
- ◆ Insufficient methodological guidance for configuration engineers
 - Guidelines exist, but: incomplete, unclear, complex, outdated
- ◆ No easy way to verify configuration
 - Tens of thousands of configuration parameters
- ◆ Manual methods for:
 - Detecting dependencies between configuration parameters
 - Detecting consequences of design changes
- ◆ Insufficient support for configuration debugging
- ◆ Insufficient support for configuration reuse
 - Clone-based reuse

Solution Approach Taken

- ♦ **Model-based engineering**
 - Formal (computer-analyzable) representation of the fully integrated system
- ♦ **Use of industry standards**
 - Modeling languages: UML, OCL, MARTE, and a custom UML profile-based configuration-specific DSL
 - Taking advantage of available expertise and tooling
- ♦ **Automation wherever possible**
 - Interactive verification of configuration choices
 - Interactive guidance through the configuration process
 - Automated enforcement of derived configuration choices

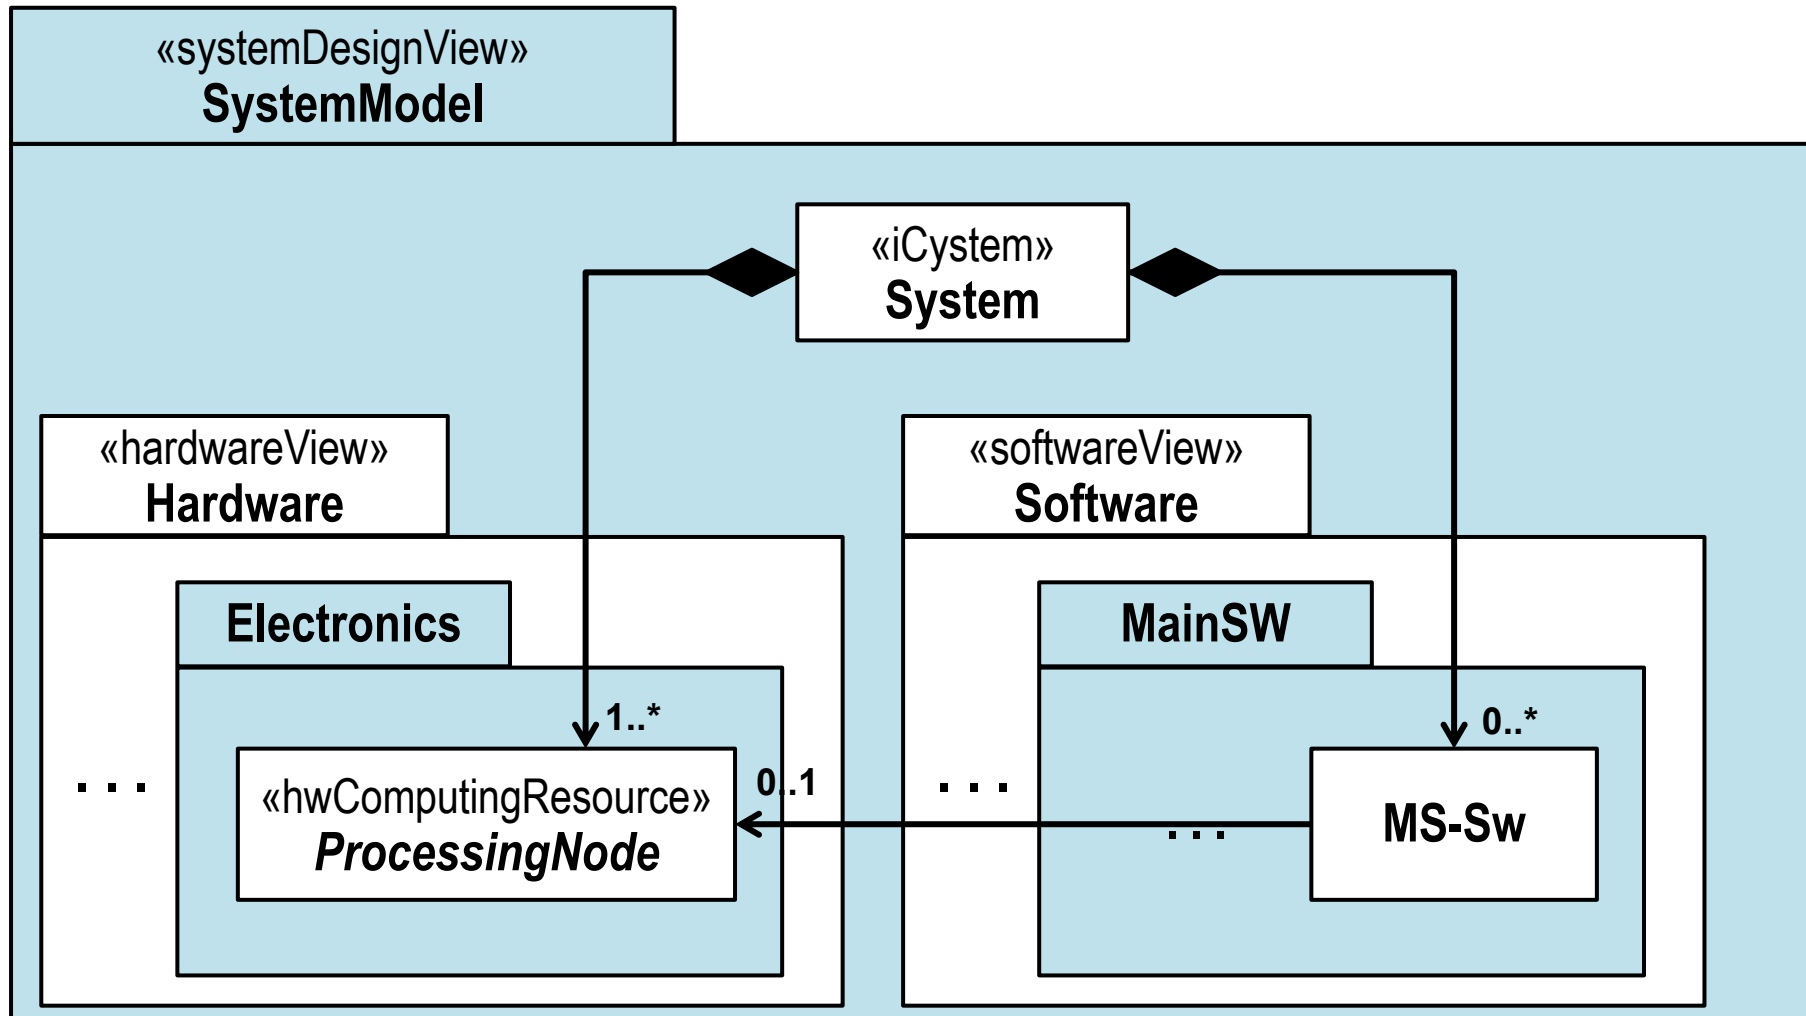

Solution Architecture

- ♦ Very similar to recent CVL standard:
 - Unfortunately, CVL was not yet available during the project

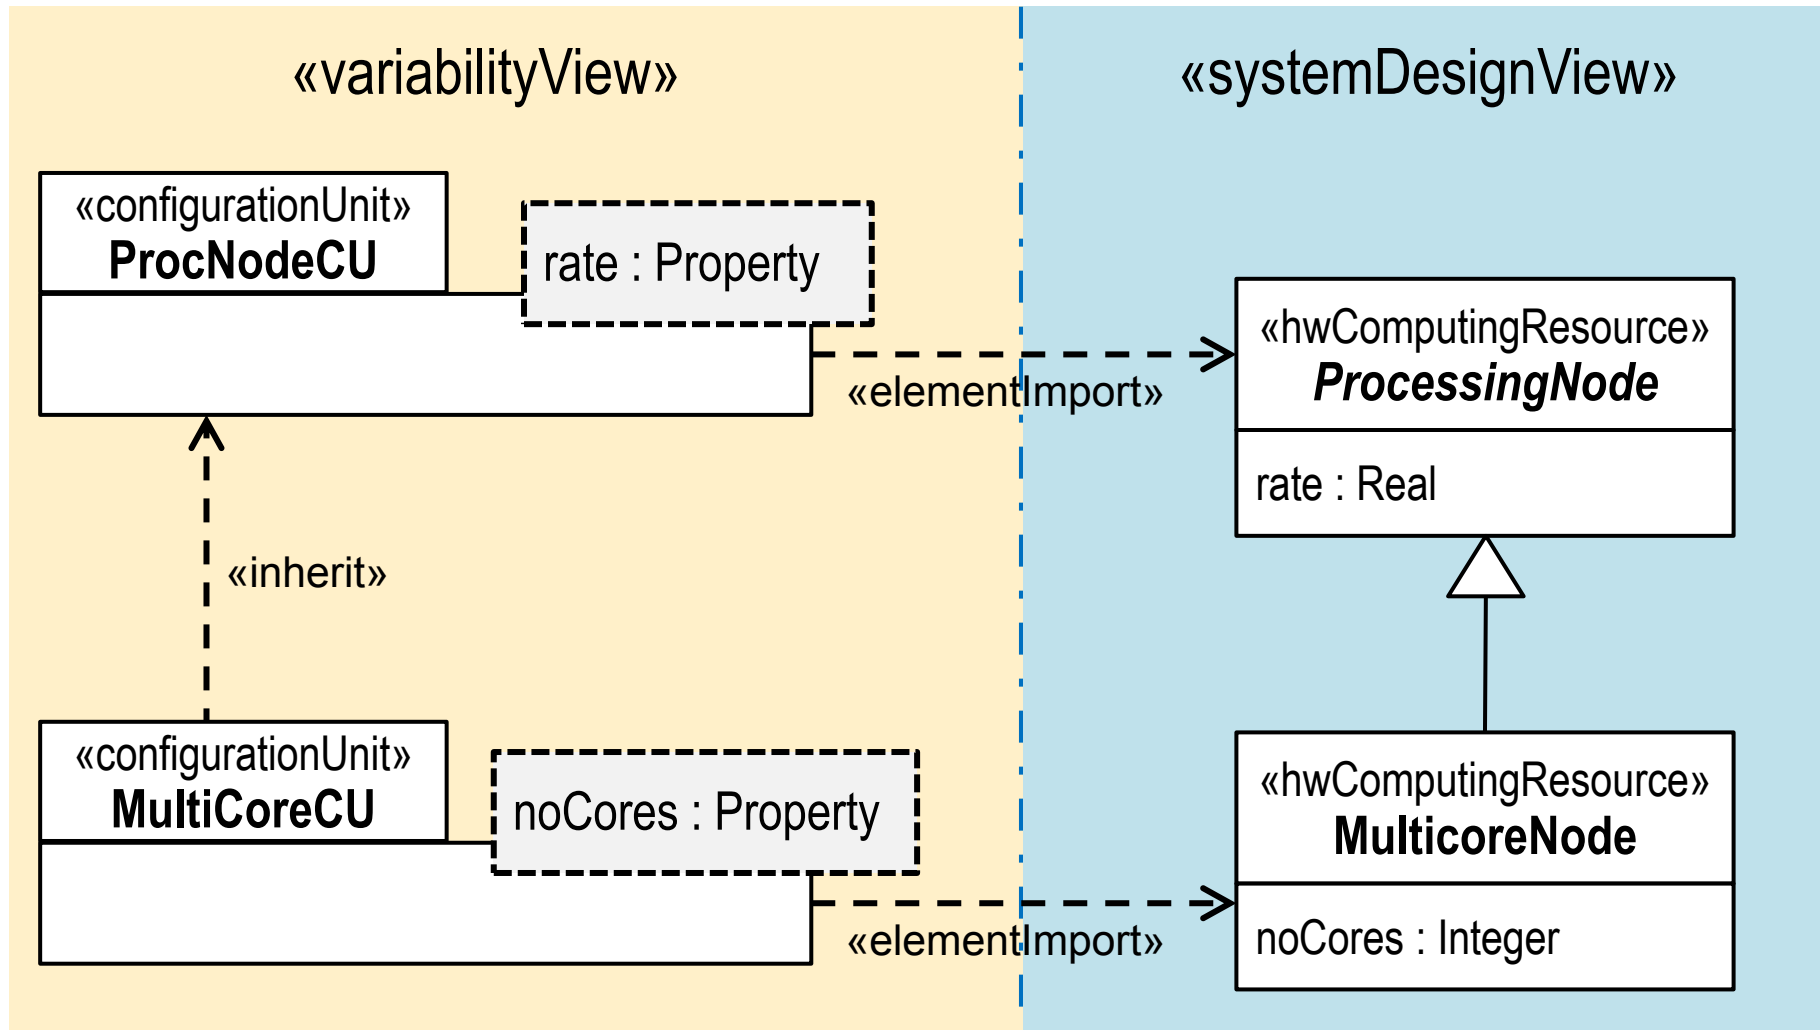

Product-Line System Model

- ◆ Using standard UML class modeling (structure only)

Variability Modeling Approach (1)

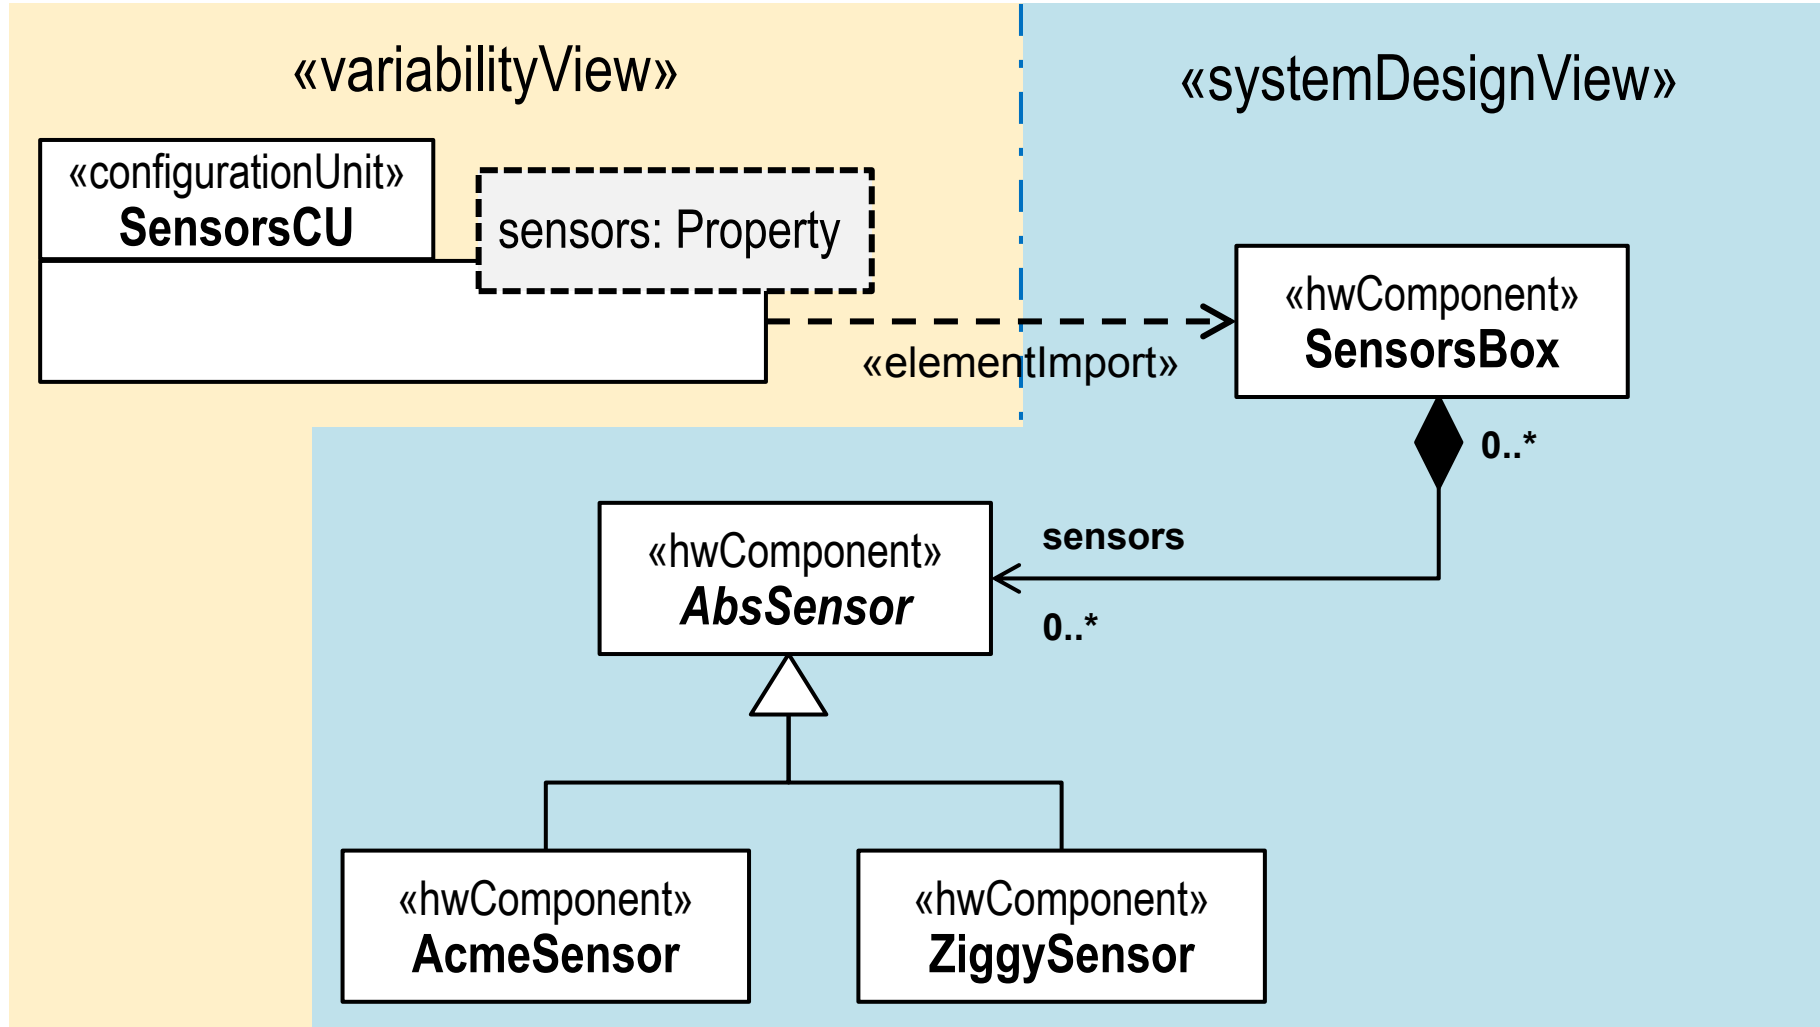

- ♦ Using the UML package template mechanism*

* NOTE: minor differences from published version

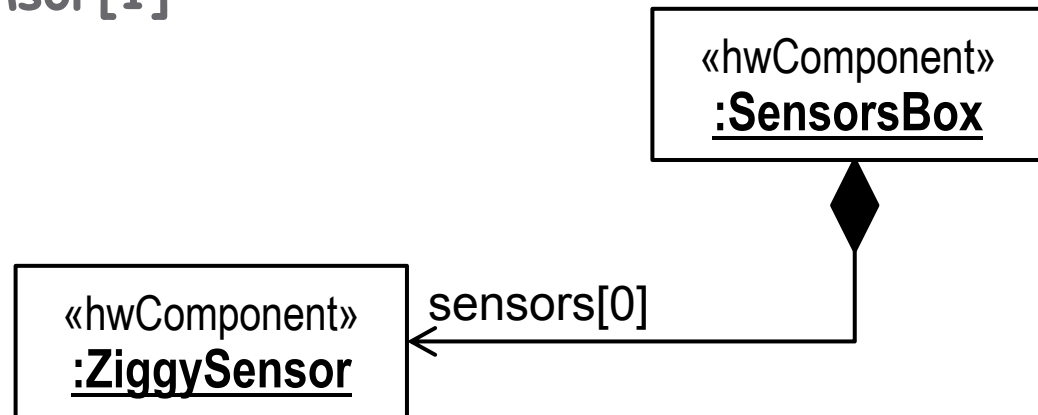

Variability Modeling Approach (2)

♦ Dealing with type variability

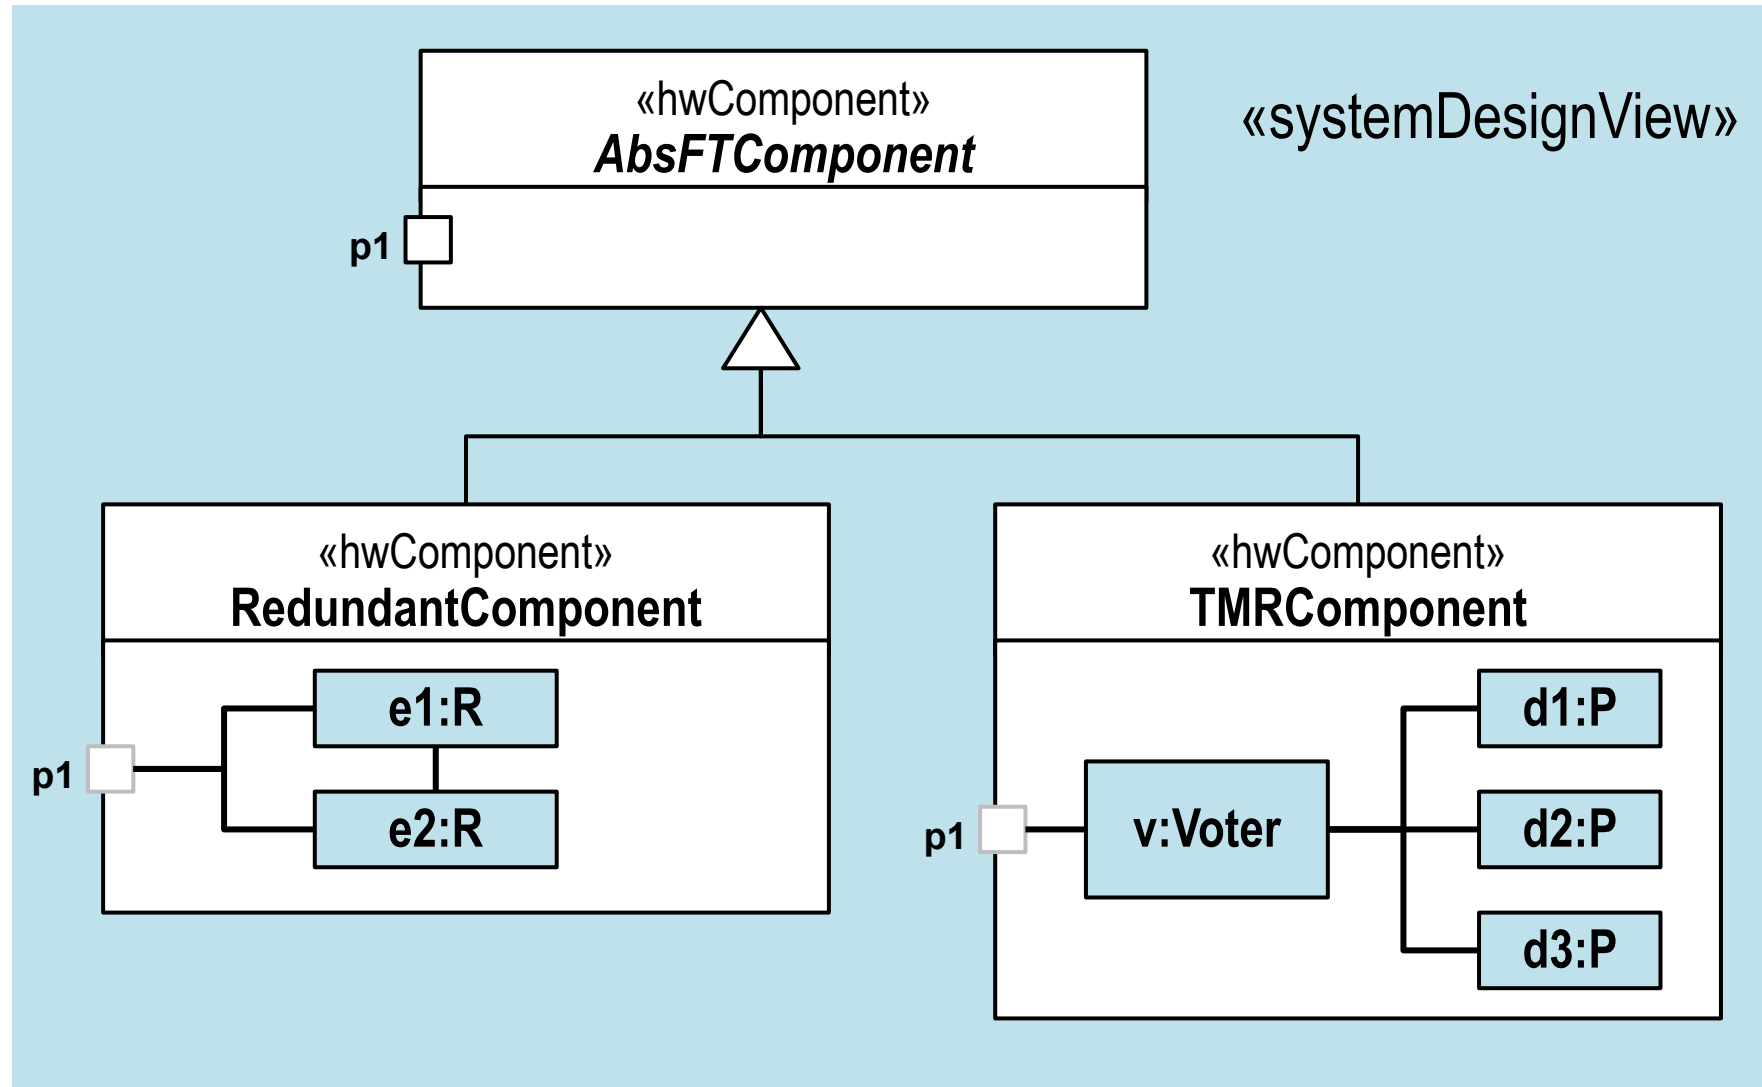

Generated Instance Model

- ♦ Generated from Configuration Specification data
- ♦ E.g., bind “sensor” template parameter to the Property:
 - `sensor:ZiggySensor[1]`

Variability Modeling Approach (3)

- ♦ Dealing with topology variability (using type variability):

Empirical Evaluation & Summary

- ♦ Approach applied to a sample product line
 - *Simplified (but representative)* product-line model of the actual system was constructed and used in the evaluation
 - Real-world product-line models had ~ 450 variability points (resulting in 10's of thousands of configuration items)
 - Evaluation model had ~100 variability points (including 16 OCL constraints)
 - A *prototype* configuration tool was produced and used
 - ♦ *All evaluation models were verified with and confirmed by domain experts*
- ⇒ Evaluation indicates that the approach has potential

Q: Was this project successful?

Detour (2): On the Effectiveness of Industry-Research Collaborations

Project Success Criteria

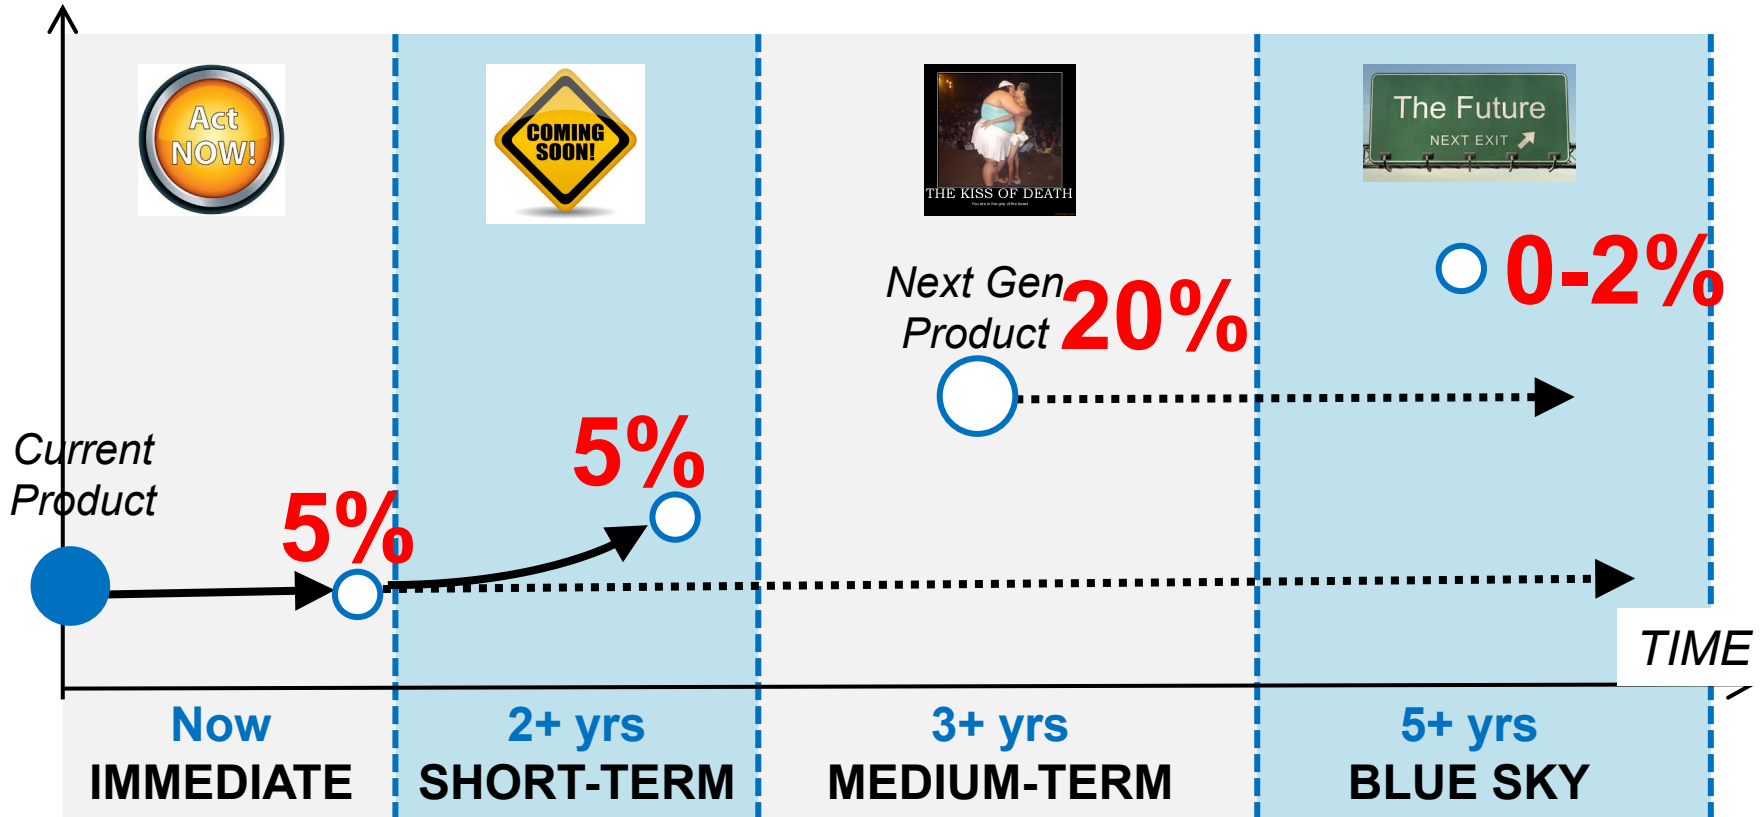

- ♦ Subset of general research objectives
- ♦ Research partner:
 - Number of publications
 - Highly-qualified personnel trained
 - Research results transferred to industry partner
 - Patents
- ♦ Industry partner:
 - Research problem resolved in a way that can be exploited
 - Productivity and/or quality improvements (e.g., reduced development costs)
 - Potential for new product opportunities analyzed and understood
 - Highly-qualified personnel hired (from research team)

The Sum of It All

- ♦ **[Opinion]:** The majority of industry-research collaborations
 - Succeed from the perspective of the research partners, particularly in independent research institutions (academia, institutes)
 - Mostly fail to meet the expectations of the industry partners
- ♦ **So, why should industry partners bother?**
 - Requires taking resources away from product groups
 - Low probability of success
 - ⇒ Funding contributions tend to be small and infrequent

Likelihood of industry Adoption

DEGREE OF
INNOVATION

♦ *CAVEAT: Opinion based on personal experience*

Key Questions

- ♦ What makes such a collaboration successful?
- ♦ How do we tell that it is likely to be successful?
- ♦ What can be done to increase the likelihood of success?
- ♦ How can we recognize projects that are unlikely to succeed?

What Is Success?

RESEARCH

*Only if the expectations
of both categories of
participants are
sufficiently met*

How Can We Predict Success?

- ♦ Realistically assess, ahead of time, the likelihood that your success criteria will be met:
- ♦ Research partner:
 - Number of publications
 - Highly-qualified personnel trained
 - Research results transferred to industry partner
 - Patents
- ♦ Industry partner:
 - Research problem resolved in a way that can be exploited
 - Productivity and/or quality improvements (e.g., reduced development costs)
 - Potential for new product opportunities analyzed and understood
 - Highly-qualified personnel hired (from research team)

How Can We Increase Likelihood of Success?

- ♦ Investigate carefully before committing
- ♦ Industry partner:
 - Evaluate research partner: are they “academically” inclined or “industrially” oriented?
 - i.e., what do they qualify as a success
 - Must be prepared to commit promised resources
- ♦ Research partner;
 - What does the industry partner qualify as a successful project?
 - [Opinion]: *SMEs and government institutions tend to be far more receptive to applying results of research compared to large enterprises*

Conclusions

- ♦ **[Opinion]** The effectiveness of industry-research collaborations in the software domain is disappointing in terms of actual technical impact
 - Only a small percentage of research results actually find their way into practice
 - Most innovation in current practice comes from within the industry's own development teams (vs. their research teams)
- ♦ **[Opinion]** The primary benefit current industry-research collaborations seems to be the creation of highly-qualified personnel (HQPs)

...and the Emperor Strutted Merrily On

- ♦ These trends are known to most of those who are directly involved – but tend to be taken for granted
- ♦ **[Opinion]** It suits those who are more interested in public perceptions than technological benefits
 - E.g., research fund dispensers, (some) researchers
- ♦ It is not going to be easy to change

Have I Oversimplified Things?

- ♦ Perhaps I have, but...

«abstraction»

- ♦ A good caricature is a typical example of good abstraction: it captures the essence and draws attention to it

Thank you, no more detours
